

Unsupervised Error Logs Clusterization

Maria Grigorieva

Scientific Research Computing Center MSU

ATLAS Software&Computing Week #63

The Key Objectives of Error Logs Clusterization

- Error logs are a fruitful source of information to diagnose and explore failures
- Diagnosing failures is a challenging problem as it requires the analysis of large amounts of textual log data without well-defined structure
- Existing approach: Human experts interpret detected log errors and create the rules (patterns of regular expressions) manually
 - Time-consuming
 - Doesn't allow to identify previously unknown error conditions automatically
- ✓ A possible solution:
 - √ to cluster log errors using methods of unsupervized text clusterization

Error Logs Exploratory Study

- ATLAS BigPanDA jobs archive
 - ~5K exeerrordiag unique messages
- Requirements
 - O Performance, suitable for the real-time applications
 - Unknown number of clusters
 - Capture outliers
 - Minimization of human intervention in the process of clusterization
 - automatic detection of clusterization parameters

Strings Clusterization Pipeline

This is the first line of this text example.

This is the second line of the same text.

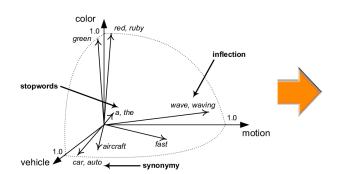

Stage 1: Tokenization

Stage 2: Vector Space Model of Words

		Dimensions					
	dog	-0.4	0.37	0.02	-0.34		
	cat	-0.15	-0.02	-0.23	-0.23		
	lion	0.19	-0.4	0.35	-0.48		
Word vectors	tiger	-0.08	0.31	0.56	0.07		
Vec	elephant	-0.04	-0.09	0.11	-0.06		
P	cheetah	0.27	-0.28	-0.2	-0.43		
š	monkey	-0.02	-0.67	-0.21	-0.48		
	rabbit	-0.04	-0.3	-0.18	-0.47		
	mouse	0.09	-0.46	-0.35	-0.24		
	rat	0.21	-0.48	-0.56	-0.37		

Words as multidimensional numerical vectors, characterized by a set of features, representing context, meaning, semantic, frequency of the words

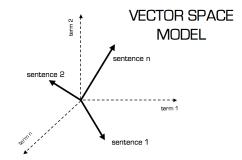

Stage 4:

Clusterization

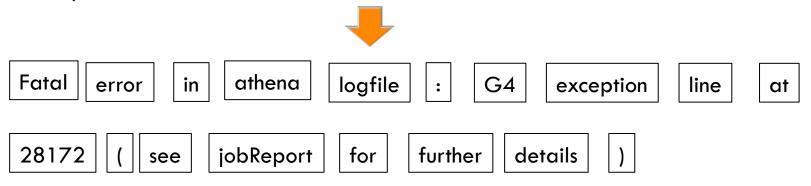

Stage 3: Vector Space Model of Sentences

Stage 1: Tokenization by Spaces and Punctuation

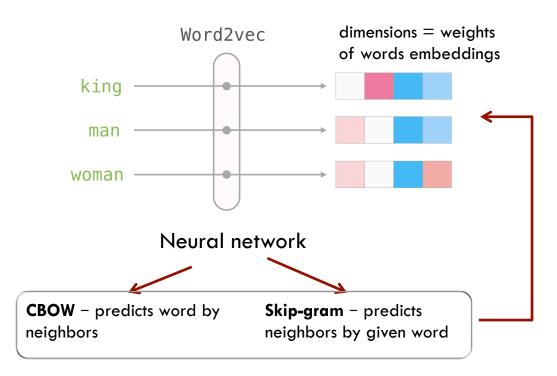

'Fatal error in athena logfile: "G4 exception at line 28172 (see jobReport for further details)"

To preserve structural information of error messages we include all punctuation and stop words in vocabulary.

Stage 2: Vector Space Model with Word2Vec (1/2)

■ The idea of Word2Vec – meaning of a word can be inferred by the company it keeps

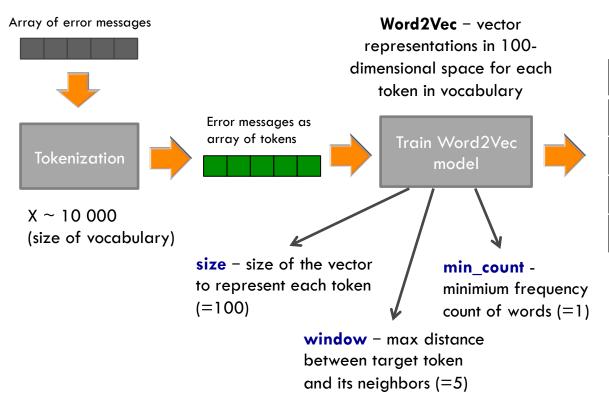

Dimensions (features) represents the variables, assigned to the words.

The selection of these features are not manual, it is automatic by using hidden layer in the training process.

Depending of the corpus the most useful dimensions are selected.

Stage 2: Vector Space Model with Word2Vec (2/2)

gensim.word2vec / python

Word2Vec Model (10 000 * 100)

		•				
	f1	f2		f100		
token1	0.98	0.33		***		
token2	0.65	0.78				
tokenX						

Stage 3: Word2Vec to Sentence2Vec Model

Advantages:

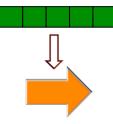

- Word2Vec retains the semantic meaning of different words in a document
- The context information is not lost
- The size of embedding vector is very small

Word2Vec Model (10 000 * 100)

	f1	f2		f100
token1	0.98	0.33		
token2	0.65	0.78	•••	
tokenX				

Word2Vec – vector representations in 100-dimensional space for each token in vocabulary.

Error messages as array of tokens

Sentence 2 Vec Model (5 000 x 100)

	fO	f1	 f100
msgl	0.98	0.33	
msg2	0.65	0.78	
msgN			

Sentence2Vec – mathematical average of the word vector representations of all the words in the sentence.

Stage 4: DBSCAN Clusterization

- Does not require to specify the exact amount of clusters in advance
- Good at identifying outliers

min_samples

the minimum number of points to form a dense region

min_samples = 1 guarantees that each outlier will be put in a separate cluster

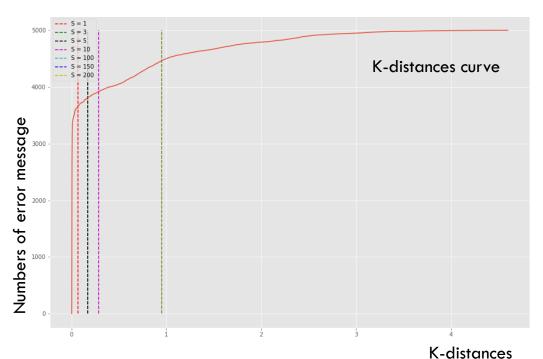

epsilon

specifies how close points should be to each other to be considered as part of a cluster

- 1) Calculate the average of the distances of every object to its k-neighbors $k = \sqrt{n}$, where n is the number of objects in dataset (rule of thumb)
- 2) Sort k-distances in an ascending order
- 3) Display k-distance curve
- 4) Find a knee where a sharp change occurs

Automatic Detection of Knee for K-distance Curve

- **Kneed** is a python library allowing to detect knees for curves automatically
- It shows knees graphically and returns knee points

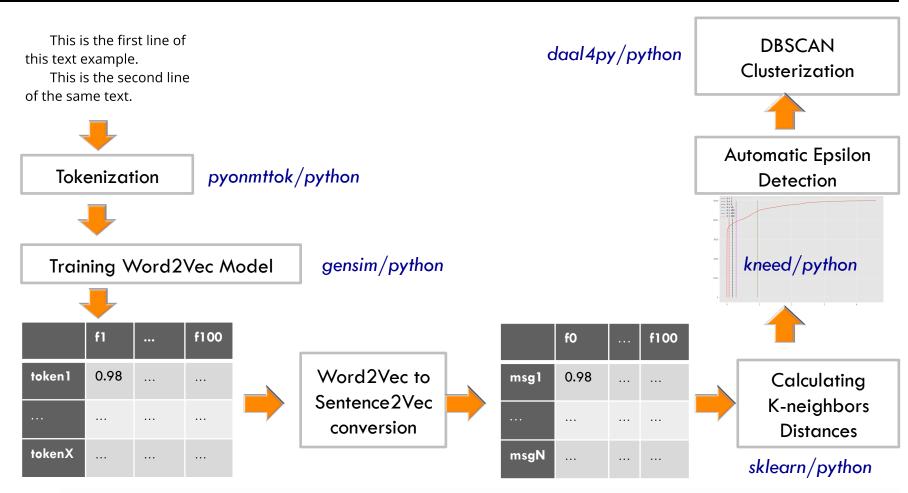

[0.06899074925405664, 0.17418354191659477, 0.17418354191659477, 0.2850125475866659, 0.9484519887921964, 0.9484519887921964, **0.9484519887921964**]

DBSCAN(min_samples=1, eps=0.94)

Error Logs Clusterization Pipeline

Clusterization of 5K Error Logs Results

71 clusters with \sim 30 outliers

Benchmarks

On data sample size up to 100K error log messages

DBSCAN sklearn / Intel DAAL

Benchmarks

Conclusion

- Unsupervised clusterization of error log messages with Word2Vec + DBSCAN with automatic detection of epsilon gives good results in quality and performance for up to 10K error logs
- Next steps:
 - Clear error log messages from unnecessary numbers, UIDs in paths
 - o Provide performance and quality tests on data from ES@Chicago for different time ranges:1h, 6h, 12h, 24h, 36h,...
 - Manual analysis of the clusterization results
 - Try another clusterization algorithms and compare results against the DBSCAN
 - Peformance optimization of k-distance search algorithm (ANN C++)
 - Deploy clusterization module at GitHub for collective use

Other methods of strings clusterization

Strings Clusterization Pipeline without Preprocessing

Array of error messages

Levenshtein distances

finding the number of edits (insert | delete | replace) which will transform one string to another

String 1		Levenshtein distance
aaa	aaa	0
aaa	aba	1
aaa	abcdefg	6

Distance Matrix (5000 x 5000)

	msg1	msg2	msg3
msg1	0	10	50
msg2	10	0	1
msg3	50	1	0

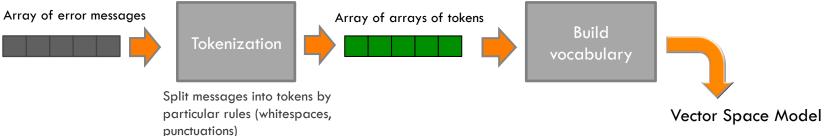

Groups of similar strings and outliers

- ☐ Advantages:
 - No need for text preprocessing
- ☐ Disadvantages:
 - Levenshtein distances are calculated very slowly
 - Levenshtein distances don't take into account strings structure
 - Clusterization results suffer of noise

Strings Clusterization Pipeline with Preprocessing

- Vector Space Model (VSM) mapping a set of strings to a set of vectors.
- The strings are characterized by a set of features, where each feature is associated with one dimension of the vector space (N-grams, tokens, ...)

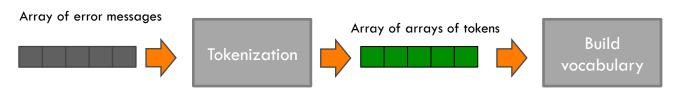

Groups of similar strings

Clusterization

Vector Space Model = TF-IDF + Cosine Similarity

☐ Advantages:

 Good at performance as log messages strings are not very long

■ Disadvantages:

TF-IDF limitations

- ignores tokens order and structure of messages
- In most cases it generates large sparse matrix (due to large vocabulary)

The resulting VSM are not satisfied for error logs, where structure of messages in crucial.

VSM = Cosine Similarity Matrix (5 000 x 5 000)

	msg1	msg2	
msg1	1.00	0.78	
msg2	0.78	1.00	
msg3	0.00	0.01	

The cosine similarity between 2 messages is a function of the angle between their vectors in the VSM.

(5 000 x 10 000)
